Subject – Cracking leaked passwords

Dear Sir/Mam,

After trying to crack all the leaked hashes, I found several vulnerabilities in your password policy and this Email concludes all the findings and suggestions to improve your password policy.

The result and analysis of my finding in context to this assessment are as follows. I have cracked the some of the leaked password using the *Hashcat* tool.

```

Hashing Algorithm used: MD5

Level of protection: MD5 (message digest algorithm) is a bad password hashing algorithm because it is too fast and memory conserving. Attacker can compute the hash of large number of passwords per second.

Recommendations to implement password:

- Try using better algorithm in place of MD5. Eg. SHA256
- Always use salts with hashes where feasible.
- For better security use slow algorithm like *bcrypt*. Which make harder for attacker because it requires more CPU cycles to authenticate user.

Observations on organization password policy:

- Weak hash functions used with no salting
- Common passwords are used which can be easily guessed and cracked
- No use of capital letters, numbers and special symbols together.

Changes to be made in password policy:

- We can increase the password length to 12 because less character's length it becomes easy for hacker to crack the password using brute force attack.
- Don't use common phrase as password. Use of mix characters.
- Check your password security with password strength checker tools and websites.

Thank you

Aman Kshetri
